

DOCUMENT FUNCTIONAL OVERVIEW

What

The Automated Network Request Management solution provides a structured process for submitting, validating, approving, and tracking network-related service requests through ServiceNow.

The solution captures the information required to process a request and routes it through the appropriate approval process based on the request's requirements and sensitivity.

Why

A defined functional structure ensures that:

- Requesters provide the information required for fulfilment.
- Requests are categorized consistently.
- Appropriate approvals are obtained before processing.
- Sensitive network requests receive additional review.
- Department-specific requests are routed to the appropriate group.
- Request processing remains standardized and traceable.

How

Request Information

The Network Request form captures relevant information through catalog variables and variable sets.

Key information includes:

Information	Purpose
Request Type	Identifies the type of network service being requested
Justification	Captures the business reason for the request
Portal Details	Provides the required service/request information through the Service Portal
Urgency	Indicates the required priority or urgency of the request

These inputs provide the information needed for downstream processing, approval, and fulfilment.

Approval Use Cases

The solution supports different approval scenarios depending on the nature of the request:

Approval Use Case	Approval Requirement	Purpose
Standard Requests	Manager Approval	Confirms that the request is authorized by the requester's management
High-Sensitivity Requests	Network Security Approval	Provides additional security review before sensitive network changes or access are processed
Department-Specific Tasks	Group Approval	Ensures that the relevant department or support group validates the request

Functional Coverage

The functional overview covers the following areas:

- **Request Submission** – Users submit Network Requests through the Service Portal.
- **Data Capture** – Required request information is collected through configured catalog variables.
- **Validation** – Mandatory fields and conditional form behavior help ensure complete information.
- **Approval** – Requests are routed for the appropriate level of authorization.
- **Notification** – Relevant stakeholders receive automated notifications.
- **Tracking** – Network request information is stored in the Network Database for monitoring and fulfilment.
- **Status Management** – Request records are updated according to the processing and approval outcome.

Outcome

The functional design provides a standardized and controlled process for network service requests, from initial submission through approval and fulfilment.

It ensures that the right information is captured, the appropriate stakeholders participate in the approval process, and requests remain visible, traceable, and manageable throughout their lifecycle.

Replicability Note

The approval use cases should be configured according to the organization's actual approval policy. Manager, network security, and group approvals should only be enabled where they correspond to the defined business requirements and implemented Flow Designer configuration.
