

INNOVATION

What

The Automated Network Request Management solution introduces a low-code automation approach for managing network service requests throughout their lifecycle.

The solution uses native ServiceNow capabilities to automate request processing while keeping customization to a minimum.

Key innovative aspects include:

- End-to-end automation using Flow Designer.
- Dynamic approval processing based on configured requirements.
- Automated record creation and updates.
- Automated email notifications.
- Conditional form behavior using UI Policies.
- Minimal use of Client Scripts, limited to essential form behavior.
- No custom Script Includes or Business Rules in the implemented solution.

Why

The solution is designed to provide automation without creating unnecessary technical complexity.

A low-code approach provides several advantages:

- Easier maintenance by ServiceNow administrators.
- Reduced dependency on custom scripting.
- Easier troubleshooting and monitoring.
- Better maintainability during future enhancements.
- Simplified knowledge transfer and handoff.
- Reduced risk of breaking custom code during configuration changes.

How

The innovation is achieved by making maximum use of native ServiceNow platform capabilities.

1. Flow Designer Automation

Flow Designer is used as the primary automation mechanism for processing Network Requests.

It handles activities such as:

- Retrieving catalog variables.
- Creating Network Database records.
- Sending notifications.
- Requesting approvals.
- Evaluating approval results.
- Updating request records.

2. Dynamic Approvals

Approval processing is configured within the automated request lifecycle, allowing requests to be routed according to the defined approval requirements.

This reduces manual coordination between requesters, approvers, and fulfilment teams.

3. Minimal Customization

Client Scripts and UI Policies are used only where required for dynamic form behavior and data population.

The implementation deliberately avoids unnecessary:

- Script Includes
- Business Rules
- Custom scripting

This keeps the solution closer to a configuration-first, low-code ServiceNow implementation.

4. Maintainability

The solution is designed so that future administrators or developers can understand and modify the configuration using standard ServiceNow tools.

This improves:

- Knowledge transfer
- Administrative handoff
- Future enhancements
- Troubleshooting
- Long-term maintainability

Outcome

The innovation of the solution lies in achieving end-to-end network request automation with minimal custom development.

By using native ServiceNow capabilities such as Flow Designer, UI Policies, Catalog configuration, approvals, and notifications, the solution provides automation while remaining simple to maintain and extend.

Innovation Summary: The project demonstrates a low-code, configuration-first approach that automates the Network Request lifecycle without relying on custom Script Includes or Business Rules. This makes the solution easier to maintain, troubleshoot, and hand over to future ServiceNow administrators or developers.
