

TROUBLESHOOTING

What

Troubleshooting covers the methods used to identify, diagnose, and resolve configuration and execution issues encountered during the implementation of the Automated Network Request Management solution.

Since the solution involves multiple interconnected components—Service Catalog, Variables, Variable Sets, UI Policies, Flow Designer, Approvals, Network Database records, and Email Notifications—issues in one component can affect the overall request lifecycle.

The following troubleshooting mechanisms were used:

- Flow Designer execution logs
- Email logs
- Variable and data-binding verification
- Service Portal form testing
- UI Policy behavior testing
- Approval-path verification
- Network Database record validation

Why

Troubleshooting is necessary to ensure that the automated request lifecycle works correctly from beginning to end.

Potential problems include:

- Flow actions failing.
- Incorrect approval conditions.
- Network Database records not being created correctly.
- Emails not being generated.
- Catalog variables not being populated.
- Auto-populated fields containing incorrect values.
- UI Policies not displaying fields as expected.
- Incorrect data being mapped between the catalog item and the Network Database table.

A systematic troubleshooting approach reduces debugging time and ensures that the final solution is reliable and reproducible.

How

Flow Execution Troubleshooting

Issue

A Network Request may submit successfully while one or more automated Flow Designer actions fail or follow an unexpected condition path.

Troubleshooting Method

1. Open **Flow Designer**.
2. Open the **Network Request** flow.
3. Navigate to the flow's **Execution Details**.
4. Open the relevant execution.
5. Review each action sequentially.
6. Check whether:
 - The trigger executed.
 - Catalog variables were retrieved.
 - The Network Database record was created.
 - Email action executed.
 - Approval action executed.
 - Approval condition evaluated correctly.
 - Update Record action executed.
7. Identify the failed action.
8. Correct the configuration.
9. Execute another test request.
10. Verify the complete execution again.

Outcome

Flow execution logs provide visibility into individual actions and conditions, making it possible to identify failures and verify that the automation follows the expected path.

Email Notification Troubleshooting

Issue

A request may be processed successfully while the expected notification is not received.

Troubleshooting Method

1. Navigate to the relevant **System Logs** → **Email** area.
2. Review the available **Sent/Received** email records.
3. Search for the notification associated with the Network Request.
4. Verify:
 - Whether the email was generated.
 - Recipient information.
 - Subject.
 - Email body.
 - Delivery/status information.
5. Compare the email execution with the corresponding Flow Designer execution.
6. If required, correct the recipient or notification configuration.
7. Submit another test request and verify the result.

Outcome

Email logs provide evidence that the notification action was triggered and allow notification-related issues to be isolated from other workflow problems.

Variable Population Troubleshooting

Issue

Catalog variables or automatically populated requester information may sometimes be missing, incorrectly mapped, or not transferred to the Network Database record.

Check the following:

1. Confirm the variable exists on the catalog item.
2. Verify the variable's **Name**.
3. Check the variable's **Order** and type.
4. Verify the Variable Set is attached to the catalog item.
5. Check the **Opened on behalf of** reference.
6. Verify that dependent fields are populated from the correct user record.
7. Check the **Get Catalog Variables** action.
8. Verify that the correct variables are selected.
9. Check the field mapping in **Create Record**.
10. Submit a new test request and verify the resulting Network Database record.

Outcome

Variable and data-binding issues can be isolated by tracing the information from the user-facing catalog form through Flow Designer to the Network Database record.

Form Behavior Troubleshooting

Issue

A field controlled by a UI Policy may not appear or disappear as expected.

For example:

Type of Connection = Existing → Enter your Existing ID should become visible.

Troubleshooting Method

1. Open the **Network Request** catalog item.
2. Open the **Catalog UI Policy**.
3. Verify that the condition is correct.
4. Open the associated **UI Policy Action**.
5. Confirm that the correct variable is selected.
6. Verify **Visible = True**.
7. Open the catalog item through the **Service Portal**.
8. Select the condition value.
9. Observe the field behavior.
10. Test the opposite condition as well.

Expected Behavior

Condition	Existing ID Field
Type of Connection = New	Hidden
Type of Connection = Existing	Visible

Outcome

Service Portal testing confirms whether the configured UI Policy and UI Policy Action are producing the intended dynamic form behavior.

Approval Troubleshooting

Because the Network Request flow includes **Ask for Approval** followed by conditional logic, approval behavior should also be verified.

Troubleshooting Checks

Verify:

1. The approval action receives the correct target record.
2. The correct approver is selected.
3. The approval request is generated.
4. The approval state changes after the approver responds.
5. The **If** condition checks the correct approval state.
6. Approved requests follow the approved branch.
7. Rejected requests follow the Else/rejected branch.
8. The Network Database record receives the appropriate status.

Troubleshooting Summary

Area	Problem Checked	Troubleshooting Method	Expected Result
Flow Execution	Failed action/incorrect path	Flow Designer Execution Details	Correct execution path
Email	Notification not generated/delivered	Email logs	Email record and status available
Variables	Missing/incorrect values	Variable Set and data-binding verification	Correct values populated
Form Behavior	Field visibility incorrect	Service Portal testing and UI Policy review	Conditional fields behave correctly
Approval	Incorrect approval path	Approval state and Flow condition verification	Approved/rejected paths execute correctly
Data Mapping	Incorrect Network Database values	Create Record field mapping review	Catalog values stored correctly

Outcome

The troubleshooting process ensures that issues across the Service Catalog, Variable Sets, UI Policies, Flow Designer, Approvals, Email Notifications, and Network Database can be systematically identified and resolved.

The approach also provides a repeatable debugging methodology for maintaining the solution after deployment.
